

Custom Format Example

This example demonstrates how to create and use a custom format in the mformat framework. The same code can be used to write to different formats, just by changing the format name.

Features

- Easy to extend the framework
 - Supports most standard document elements
 - Format-agnostic API
1. First step: Create a format class
 2. Second step: Implement required methods
 3. Third step: Register the format

Element	Method
Paragraph	new_paragraph()
Heading	new_heading()
List	new_bullet_item()

```
def example():  
    print("Hello, World!")
```

This text is **bold** and this is *italic*.
